

Python introduction

In order for us to learn the basics of Python, we created a simple program with Python. It's pretty basic, since the most it does is display data introduced by the user and then display it in order. The real objective of this program is to learn the types of strings and data

The data that the program displays are the full name of the user, their age, height, weight, phone number and whether the user has a driving license or not. The program uses Numbers, text strings and Boolean data. The Boolean data refers to "True/False" information. The program makes use of just constants, since any kind of data is modified during the run.
